

J3314-15 January 2015 Supercedes J3314 Released March 2010

Driveshafts for Industrial Applications

**Dana: Driveshaft engineering experts** For more than 100 years, Dana's expertise and worldwide network of manufacturing partnerships have sustained its ability to supply economically efficient, high-performance products to original equipment manufacturers (OEMs) in changing market environments.

With a focus on technical innovation, quality performance, reliability, and flexibility, Dana engineers continue to provide customers with the same quality and support they've come to expect.

Since 1946, Dana's GWB® driveshafts have been known for global innovation and quality performance. GWB® heavy driveshafts were the first to be developed specifically for diesel locomotives. In the 1950s, GWB® driveshafts were the largest available at that time, and were followed several decades later by the first maintenance-free driveshaft. Based on a long-standing commitment to continual innovation and customer satisfaction, GWB® driveshafts have been recognized as a market

leader throughout the world.

GWB® driveshafts include a wide range of products for multiple applications, covering a torque range from 2,400 to 16,300,000 Nm.

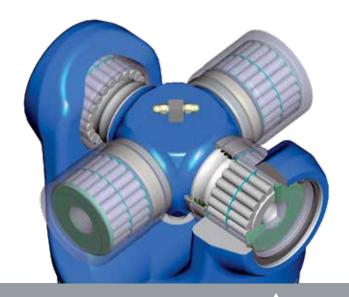

Today, there are basically two types of driveshafts that have evolved into a worldwide technology standard. Their main difference lies in the design of the bearing eye.

Closed bearing eye: This is a design used mainly in the commercial vehicles sector and for general mechanical engineering applications (series 687/688 and 587).

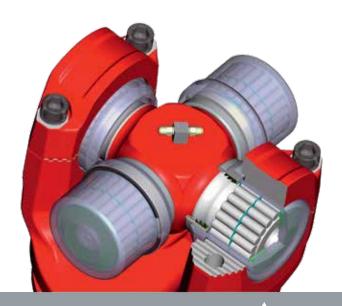

**Split bearing eye:** Developed for heavy and super-heavy duty applications, this design (series 390/392/393 and 492/498), provides compact dimensions in

conjunction with a maximum torque transmission capability and greatly improved service life, apart from facilitating maintenance and assembly operations.

# 2,400 - 16,300,000 Nm

Split bearing eye

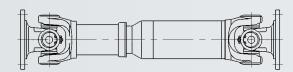

### **Series**

### 687/688

Torque range TCS from 2.4 to 35 kNm

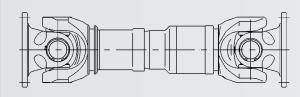

Flange diameter from 100 to 225 mm

### 587

Torque range TCS from 43 to 57 kNm

Flange diameter from 225 to 285 mm

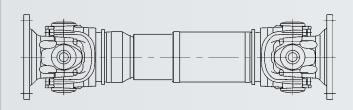

# 390

# Maximum bearing life

Torque range TCS from 60 to 255 kNm

Flange diameter from 285 to 435 mm

# **Design features**

- Closed bearing eyes
- Compact design
- Low maintenance
- Plastic-coated splines
- Operating angle up to 25°, partly up to 44°

# **Preferred applications**

- Railway vehicles
- Rolling mill plants
- Marine drives
- General machinery construction plants

Technical data (refer to data sheets)

- Closed bearing eyes
- Compact design
- Low maintenance
- Splines coated with lubricating varnish (587.50 – plastic-coated)
- Operating angle up to 24°

- Railway vehicles
- Rolling mill plants
- Marine drives
- General machinery construction plants

Technical data (refer to data sheets)

- Maximum bearing life in confined spaces
- Split bearing eyes with toothed bearing cap
- Compact design
- Optimized roller bearing
- Length compensation coated with lubricating varnish
- Operating angle up to 15°

- Railway vehicles
- Marine drives
- Crane systems
- Paper machines
- General machinery construction plants

Technical data (refer to data sheets)

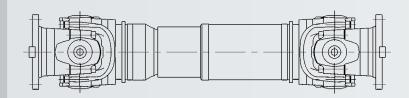

### **Series**

### 392/393

High torque capacity/ optimized bearing life

Torque range TCS from 70 to 1,150 kNm

Flange diameter from 225 to 550 mm

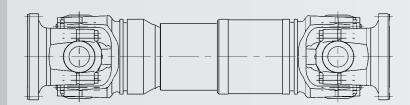

### 492

# Maximum torque capacity

Torque range TCS from 210 to 1,300 kNm

Flange diameter from 285 to 550 mm

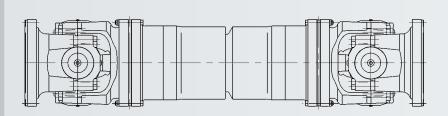

# 498

# Larger sizes available on request

Torque range TCS from 1,880 to 15,000 kNm

Flange diameter from 600 to 1,200 mm

# **Design features**

- High torque capacity despite small connecting dimensions
- Split bearing eyes with toothed bearing cap
- Compact design
- Journal cross with low notch factor
- Length compensation coated with lubricating varnish
- Operating angle 10° up to 15°
- Series 393 with optimized bearing life
- Increased torque capacity in comparison to 393
- Split bearing eyes with toothed bearing cap
- Standard Hirth-serrated flange
- Journal cross with low notch factor
- Length compensation coated with lubricant varnish
- Operating angle 7° up to 15°
- Three operating angle versions for maximum torque or maximum bearing life capacity
- Split bearing eyes with toothed bearing cap
- Standard Hirth-serrated flange
- Operating angle up to 15°

# **Preferred applications**

- Rolling mill plants
- Calender drives
- Heavy-loaded plants of general machinery construction

Technical data (refer to data sheets)

- Rolling mill plants
- Calender drives
- Extremely high loaded plants of general machinery construction

Technical data (refer to data sheets)

- Main rolling mill drive units
- Heavy machinery construction plants

Technical data (refer to data sheets)

# **Special designs of GWB® driveshafts and additional equipment**

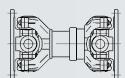

**Series** 

### 587/190

### Super short designs

Torque range TCS from 23 to 94 kNm

Flange diameter from 275 to 405 mm

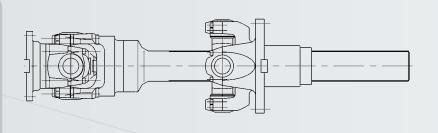

### 392/393

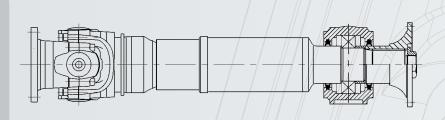

### **Tunnel joint shafts**

Torque range TCS from 57 to 1,053 kNm

Flange diameter from 225/315 to 550/710 mm

# Intermediate shafts

# **Special designs of GWB® driveshafts** and additional equipment

### **Design features**

- Closed bearing eyes (series 587)
- Split bearing eyes (series 190)
- Joints and length compensation are regreasable
- Operating angle up to 5°

# **Preferred applications**

- Railway vehicles
- Rolling mill plants
- Marine drives
- Calender drives
- Paper machines
- General machinery construction plants

Technical data (refer to data sheets)

- Shorter designs with large length compensation
- Length compensation through the joint
- High torque capacity with small connection dimensions
- Split bearing eyes with toothed bearing cap
- Bearings with labyrinth seals
- Operating angle up to 10°/7.5°

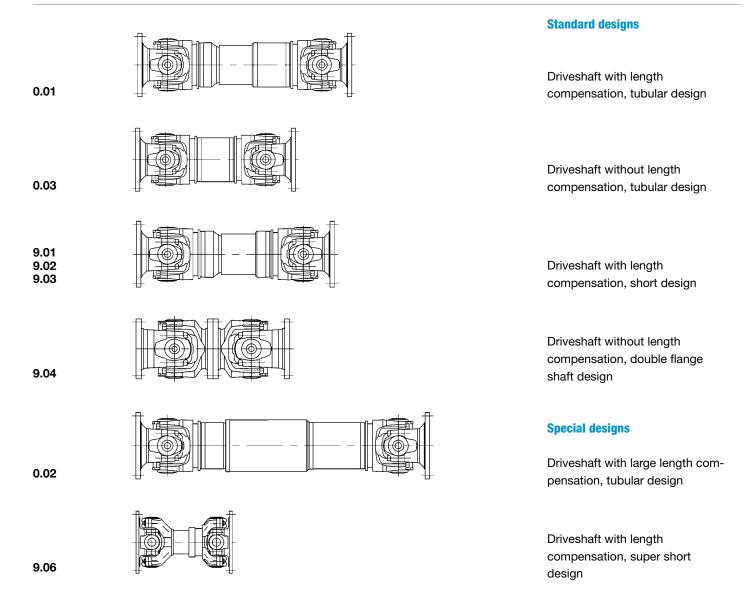

Rolling mill plants

- With or without length compensation
- Integrated bearing location

Pump drives

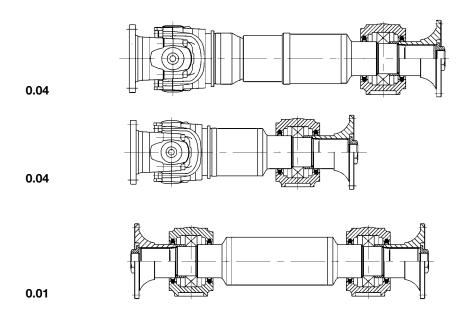

# **Notations for reviewing data sheets**

# Intermediate shafts\*

(available with intermediate bearing on request)

Intermediate shaft with length compensation

Intermediate shaft without length compensation

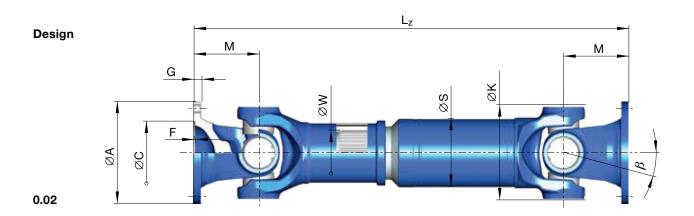

Midship shaft

\* Data sheet and/or drawing available on request.

- 0.02 with length compensation, tubular design
- 0.03 without length compensation, tubular design
- 9.01 with length compensation, short design

- 9.03 with length compensation, short design
- 9.04 without length compensation, double flange shaft design

### T<sub>CS</sub> = Functional limit torque\*

If the permissible functional limit torque  $T_{CS}$  is to be fully utilized, the flange connection (e.g., with dowel pins) must be reinforced. Yield torque 30% over  $T_{CS}$ 

T<sub>DW</sub> = Reversing fatigue torque\*
L<sub>c</sub> = Bearing capacity factor\*

See specifications of driveshafts.

= Maximum deflection angle per joint

4) 390.60 - 390.70 + 0.2 mm 390.75 - 390.80 + 0.5 mm

<sup>1)</sup> Effective spigot depth

<sup>2)</sup> Number of flange holes (standard flange connection)

<sup>3)</sup> Number of flange holes (dowel pin connection)

### **Operating instructions**

### Engaging and disengaging the coupling

Engaging and disengaging are done by operating the threaded spindle located in the inner part of the coupling. The spindle can be reached from two sides and be operated. The spindle is tightened by means of a socket wrench (see table).

### Notice:

1. Before engaging the coupling, make sure that the coupling teeth are properly fitted.

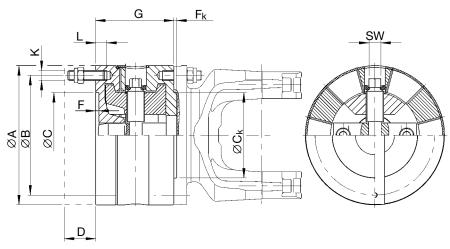

- 2. The engagement direction is marked by arrows. The spindle may be tightened either clockwise or counterclockwise.
- 3. The joint with the coupling component falls back when disengaged. **Caution: Danger of injury!**

In case of a subsequent installation of the quick release coupling, the driveshaft must be correspondingly shorter. The threaded spindles of the coupling are lubricated by the supplier with MoS<sub>2</sub>. Relubrication is recommended at least 2 times per year.

# Data sheet Standard companion flanges

Standard companion flanges can be manufactured with cylindrical bore holes and face keyway (material C45; hardened and tempered 750 – 900 N/mm²) on request. For designs deviating

from the standard, e.g., oil pressure connection, conical bore, flat journal, and material, relevant drawings are required.

## **General theoretical instructions**

### **Kinematics of Hooke's joints**

### 1. The joints

In the theory of mechanics, the cardan joint (or Hooke's joint) is defined as a spatial or spherical drive unit with a non-uniform gear ratio or transmission. The transmission behavior of this joint is described by the following equation:

$$\alpha_2 = \arctan\left(\frac{1}{\cos\beta} \cdot \tan \alpha_1\right)$$

 $\begin{array}{ll} \beta & = \text{Deflection angle of joint } [\c \diamond^\circ] \\ \alpha_1 & = \text{angle of rotation drive side} \\ \alpha_2 & = \text{angle of rotation driven side} \end{array}$ 

In this equation,  $\alpha_2$  is the momentary rotation angle of the driven shaft 2. The motion behavior of the driving and the driven ends is shown in the following diagram. The asynchronous and/or non-

homokinematic running of the shaft 2 is shown in the periodical oscillation of the asynchronous line  $\alpha_2$  around the synchronous line  $\alpha_1$  (dotted line).

A measure for the non-uniformity is the difference of the rotation angles  $\alpha_2$  and  $\alpha_1$  or the transmission ratio of the angular speeds  $\omega_2$  and  $\omega_1$ . Expressed by an equation, that means:

2

$$\phi_K = \alpha_2 - \alpha_1$$

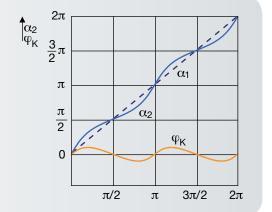

(also called gimbal error)

$$\phi_{K} = \arctan\left(\frac{1}{\cos\beta} \cdot \tan \alpha_{1}\right) - \alpha_{1}$$

$$\phi_{\text{K max.}} = \arctan\left(\frac{\cos\beta - 1}{2\sqrt{\cos\beta}}\right)$$

b) Ratio:

$$i = \frac{\omega_2}{\omega_1} = \frac{\cos\beta}{1 - \sin^2\beta \cdot \cos^2\alpha_1}$$

## **General theoretical instructions**

The following diagram shows the ratio  $i = \omega_2/\omega_1$  for a full revolution of the universal joint for  $\beta = 60^\circ$ .

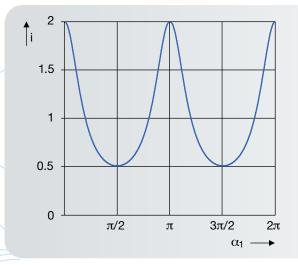

The degree of non-uniformity U is defined by:

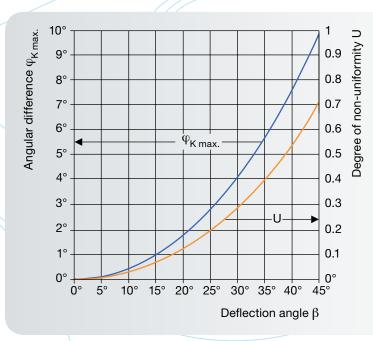

$$U = i_{max.} - i_{min.} = tan\beta \cdot sin\beta$$

Where:

$$i_{max.} = \frac{1}{\cos\beta}$$

 $i_{min.} = cos\beta$ 

The diagram shows the course of the degree of non-uniformity U and of the angular difference  $\phi_{K\,max.}$  as a function of the deflection angle of the joint from 0 to 45°.

From the motion equation it is evident that a homokinematic motion behavior corresponding to the dotted line under  $45^{\circ}$  – as shown in the diagram – can only be obtained for the deflection angle  $\beta=0^{\circ}$ . A synchronous or homokinematic running can be achieved by a suitable combination or connection of two or more joints.

#### 2. The universal shaft

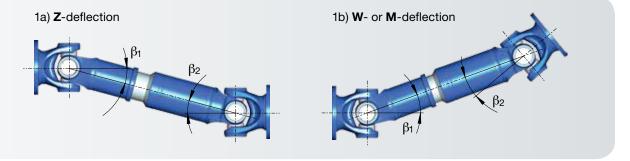

The rotation angle difference  $\Psi_K$  or the gimbal error of a deflected universal joint can be offset

under certain installation conditions with a second universal joint.

The constructive solutions are the following:

1. The deflection angles of both joints must be equal (i.e.,  $\beta_1 = \beta_2$ )

Two arrangements are possible:

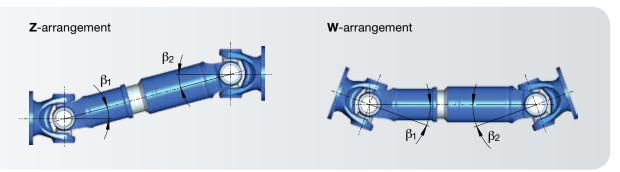

2. The two joints must have a kinematic angular relationship of  $90^{\circ}$  ( $\pi$ /2), (i.e., the yokes of the connecting shaft are in one plane).

For a more intensive study of universal shaft kinematics, please refer to the VDI-recommendation 2722 and to the relevant technical literature.

#### **Operating angles**

The most common arrangements are the Z- and W-deflections. To begin, consider the system in which the shafts to be connected are in the same plane.

## Maximum permissible angle difference

The condition  $\beta_1 = \beta_2$  is one of the essential requirements for a uniform output speed condition and cannot always be fulfilled. Therefore, designers and engineers will often ask for the permissible difference between the deflection angles of both joints.

The deflection angles for hightorque and high-speed machine drives should be equal. If not, the difference should be limited to 1° to 1.5°.

Greater differences of about 3° to 5° are acceptable without disadvantages in low-speed applications. For applications with varying deflection conditions, it is important to obtain uniformity, if possible, over the complete deflection range.

Deflection in two planes means that the deflection is both horizontal and vertical. The combination of two identical types of deflection (Z/Z or W/W) and identical deflection angles ensure uniformity. For a combination of Z- and W-deflection, the inner yokes must be offset. Please consult with Dana application engineers to determine the proper amount of angular offset.

Determination of the maximum permissible operating deflection angle  $\boldsymbol{\beta}$ 

Depending on the driveshaft series, the maximum deflection angle per joint is  $\beta = 5^{\circ}$  to 44°. Due to the kinematic conditions of the cardan joint, as described before, the deflection angle must be limited in relation to the speed.

Calculations and observations of many applications have shown that certain mass acceleration torques of the center part must not be exceeded in order to guarantee smooth running of the drive systems. This acceleration torque depends on the

## Product of speed and deflection angle D = $n \cdot \beta$

and the moment of inertia of the middle part of the shaft. The parameter D is proportional to the angular acceleration of the driveshaft center part  $\mathcal{E}_2$ .

$$\mathcal{E}_2 \sim \mathbf{D} = \mathbf{n} \cdot \boldsymbol{\beta}$$

n = Operating speed [rpm]

 $\beta$  = Deflection angle of joint [ $\d$ °]

 $\mathcal{E}_2$  = Angular acceleration of driveshaft center part

The maximum permissible deflection angle at a given speed and an average driveshaft length can be determined from the following diagram.

For an exact determination, contact Dana.

Limits for the product of operating speed and deflection angle

#### **Speed**

## Checking the critical torsional speed

The plant or vehicle manufacturer has to prevent the use of drive-shafts within the critical torsional speed ranges of the drive. Therefore, the determination of the critical torsional speed ranges of the drive system is required. The values for the moment of inertia and torsional stiffness of the selected driveshaft can be taken from the data sheets or be supplied upon request.

## Checking the critical bending speed

Except for short and rigid designs, driveshafts are flexible units with critical bending speeds and flexural vibrations that have to be checked. To accomplish this, the first and possibly second order critical bending speeds are important.

For safety reasons, the maximum permissible operating speed must be at a sufficient distance from the critical bending speed.

### $n_{perm. max. \simeq} 0.8 \cdot n_{crit.} [rpm]$

The critical bending speed for a particular shaft size is deter-mined by the length and the tube diameter only (see diagram). For greater length dimensions, the tube diameter has to be increased. The diameter is limited because of the ratio to the shaft size. Therefore, single driveshafts can only be provided up to a certain length. All installations exceeding this limit have to be equipped with subdivided drive lines.

# For determination of the critical bending speed, see the following selection diagrams.

These diagrams only apply to driveshafts that are installed with solid bearing supports located close to the flange.

Different installations (e.g., units with elastic mounting bearing) must have lower critical bending speeds.

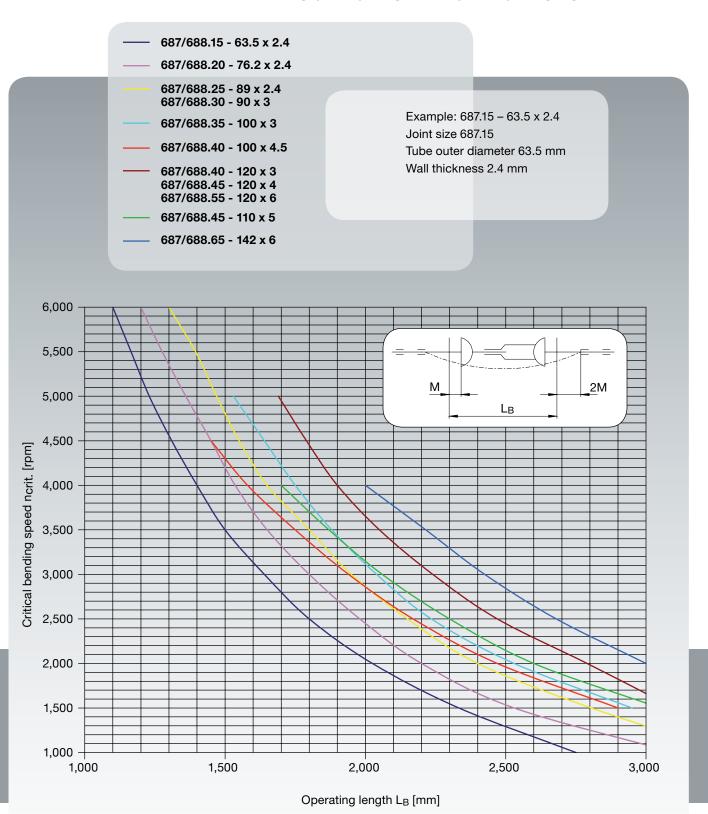

Depending on the type of the plant, excitations of second order can cause flexible vibra-tions. Please contact Dana engineers if the deflection angle exceeds 3° and for greater length dimensions.

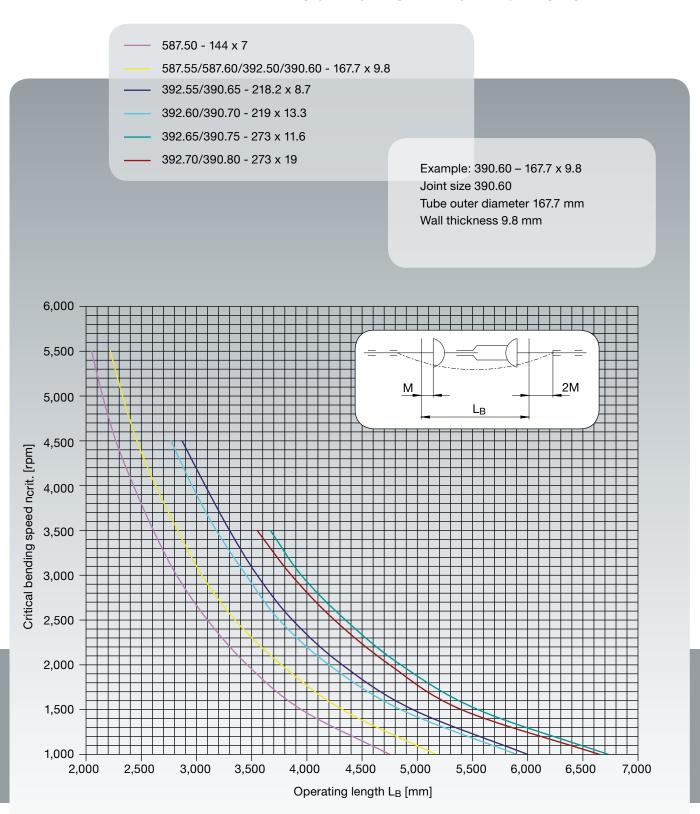

**Series 687/688** 

Determination of the critical bending speed depending on the respective operating length

Series 587/390/392

Determination of the critical bending speed depending on the respective operating length

### **Length dimensions**

The operating length of a driveshaft is determined by:

- the distance between the driving and the driven units
- the length compensation during operation

The following abbreviations are used:

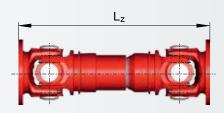

#### Lz = Compressed length

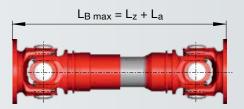

This is the shortest length of the shaft. A further compression is not possible.

#### La = Length compensation

The driveshaft can be expanded by this amount. An expansion beyond that dimension is not permissible.

 $L_z + L_a = Maximum permissible$ operating length  $L_{Bmax}$ .

During operation, the driveshaft can be expanded up to this length. The optimum working length L<sub>B</sub> of a driveshaft is achieved if the length compensation is extracted by onethird of its length.

## $L_{B} = L_{z} + \frac{1}{3}L_{a} \quad [mm]$

This general rule applies to most of the arrangements. For applications where larger length alterations are expected, the operating length should be chosen in such a way that the movement will be within the limit of the permissible length compensation.

#### **Arrangements of driveshafts**

A tandem arrangement of driveshafts could become necessary to cope with greater installation lengths.

Basic forms of shaft combinations:

Driveshaft with intermediate shaft

Driveshaft with two intermediate shafts

Two driveshafts with double intermediate bearing

In such arrangements, the individual yoke positions and deflection angles should be adjusted with regard to one another in such a way that the degree of non-uniformity (see General theoretical instructions) and the reaction forces acting on the connection bearings (see Technical instructions for application) are minimized.

## Load on bearings of the connected units

#### **Axial forces**

For the design of a driveshaft, it must be taken into account that axial forces can occur. These forces must be absorbed by axial thrust bearings of the connected units.

Axial forces will occur during length variations in the driveshaft. Additional axial forces are caused by increasing torque and by increasing pressure during lubrication of the splines. These forces will decrease automatically and can be accelerated by the installation of a relief valve.

The axial force  $A_k$  is a combination of two components:

#### 1. Frictional force FRL

This is the force that occurs in the length compensation. It can be determined from:

$$F_{RL} = T \cdot \frac{\mu}{r_m} \cdot \cos \beta$$

F<sub>RL</sub> = Frictional force from the length compensation [N]

It depends on:

- T = Torque of the driveshaft [Nm]
- r<sub>m</sub> = Pitch circle radius in the sliding parts of the driveshaft [m]
- μ = Friction coefficient (depends on spline treatment):
  - 0.08 for plastic-coated splines
  - 0.11 for steel/steel (greased)
- $\beta$  = Operating deflection angle

#### 2. Power Fp

This force occurs in the length compensation due to the increasing pressure in the lubrication grooves of the driveshaft.

The force depends on the lubrication pressure (maximum permissible pressure is 15 bar).

### Dana's environmental protection management policy

An important feature of Dana's environmental protection management policy is dedication to product responsibility. Because of this commitment, the effect of driveshafts on the environment is given considerable attention. GWB® driveshafts are lubricated with lead-free grease, their paint finishes are low in solvents and free of heavy metals, and they are easy to maintain. After use, they can be introduced into the recycling process.

### **Balancing of driveshafts**

The balancing of driveshafts is performed to equalize eccentrically running masses, therefore preventing vibrations and reducing the load on any connected equipment.

Balancing is carried out in accordance with ISO Standard 1940, "Balance quality of rotating rigid bodies". According to this standard, the permissible residual unbalance is dependent on the operating speed and mass of the balanced components.

Dana's experience has shown that balancing is not normally required for rotational speeds below 500 rpm. In individual cases, this range may be extended or reduced, depending on the overall drivetrain characteristics.

Driveshafts are balanced in two planes, normally to a balancing accuracy between G16 and G40.

### Balancing speed

The balancing speed is normally the maximum speed of the system or vehicle.

#### Quality grade

In defining a quality grade, it is necessary to consider the reproducibility levels achievable in the customer's own test rig during verification testing. Quality grades are dependent on the following variables:

- Type of balancing machine (hard, rigid or soft suspension)
- Accuracy of the measuring system
- Mounting tolerances
- Joint bearing radial and axial play
- Angular backlash in longitudinal displacement direction

Field analyses have shown that the sum of these factors may result in inaccuracies of up to 100%. This observation has given rise to the definition of the following balancing quality grades:

- Producer balancing: G16
- Customer verification tests:
   G32

## Selection of GWB® driveshafts

The design of driveshafts must exclude all possible danger to people and material by secured calculation and test results, as well as other suitable steps (see Installation and Maintenance/ Safety Instructions).

The selection procedure described on these pages is only a general recommendation. Please consult Dana engineers for the final design for your application.

The selection of a driveshaft should be based on the following conditions:

- 1. Specifications of driveshafts
- 2. Selection by bearing life
- 3. Operational dependability
- 4. Operating angles
- 5. Speed
- 6. Length dimensions
- 7. Load on bearings of the connected units

### 1. Specifications of driveshafts

## T<sub>CS</sub> = Functional limit torque [Nm]

Up to this maximum permissible torque, a load may be applied to a driveshaft for a limited frequency without the working capability being affected by permanent deformation of any driveshaft functional area. This does not result in any unpermissible effect on bearing life.

#### Yield torque

This torque level leads to irreversible plastic deformation of the driveshaft which could result in a failure of the complete drive system.

## T<sub>DW</sub> = Reversing fatigue torque [Nm]

At this torque, the driveshaft is permanently solid at alternating loads. The values for driveshafts of series 687/688 with welded balancing plates are lower. With a fatigue torque of this order, the transmission capacity of the flange connection must be checked.

## T<sub>DSch</sub> = Pulsating fatigue torque [Nm]

At this torque, the driveshaft is permanently solid at pulsating loads.

#### $T_{DSch} = 1.4 \cdot T_{DW}$

### L<sub>C</sub> = Bearing capacity factor

The bearing capacity factor takes into consideration the dynamic service life  $C_{dyn}$  (see DIN/ISO 281) of the bearings and the joint geometry R. The  $L_C$  values for the different shaft sizes are shown in the tables (see data sheets).

When selecting driveshafts, the bearing life and the operating strength must be considered separately. According to the load state, the reversing fatigue torque T<sub>DW</sub> or the pulsating fatigue torque T<sub>DSch</sub> must also be taken into consideration.

## Selection of GWB® driveshafts

### 2. Selection by bearing life

### By bearing capacity factor L<sub>C</sub>

The bearing life L<sub>h</sub> of a driveshaft depends on the bearing capacity factor and is based on the following formula:

$$L_h = \frac{L_C \cdot 10^{10}}{n \cdot \beta \cdot T^{10/3} \cdot K_1}$$

If the desired bearing life  $L_h$  is given, the joint size can be calculated by the bearing capacity factor  $L_C$ .

$$L_C = \frac{L_h \cdot n \cdot \beta \cdot T^{10/3} \cdot K_1}{10^{10}}$$

The L<sub>C</sub> values can be taken from the tables (see data sheets).

L<sub>C</sub> = Bearing capacity factor

n = Operating speed [rpm]

 $\beta$  = Operating deflection angle [ $\uparrow$ °]

T = Operating torque [kNm]

 $K_1$  = Shock factor

If operating data are based on a duty cycle, a more precise durability can be calculated.

Drives with internal combustion engines may cause torque peaks that must be considered by factor K<sub>1</sub>.

Electric motor/turbine  $K_1 = 1.00$ Gasoline engine

4 cylinder and more  $K_1 = 1.15$ Diesel engine

4 cylinder and more  $K_1 = 1.20$ 

The values shown in the tables are general values. If a flexible coupling is used, the shock factor is lower. Principally the data of the motor and/or coupling manufacturer must be observed.

#### 3. Operating dependability

The operating dependability can be determined if a certain duty cycle is given. The calculated service life of a driveshaft under normal working conditions has to achieve or exceed the required service life.

Calculations are based on the peak torque T and the maximum peak torque T<sub>SP</sub> that may occur. The peak torque is determined

than 60 years of experience as

provide an optimal selection.

a manufacturer of driveshafts to

according to the type of operation and the torque characteristic. It should be lower than the corresponding torques

TDSch and TDW.

 $T_N \cdot K = T < T_{DSch} \ or \ T_{DW}$ 

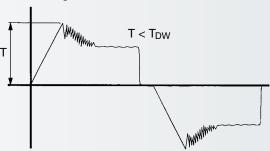

## Selection of GWB® driveshafts

Typical types of torques:

### Pulsating stress

### Alternating stress

The maximum peak torque T<sub>SP</sub> is the extremely rarely occurring torque of the system (crash, emergency case).

This maximum torque ( $T_{SP}$ ) should not exceed the functional limited torque  $T_{CS}$  of the driveshaft.

#### $T_{SP} < T_{CS}$

T<sub>SP</sub> = Maximum peak torque [Nm]
T<sub>N</sub> = Nominal torque [Nm]
T<sub>CS</sub> = Functional limit torque of the driveshaft [Nm] (see data sheets)

#### Light shock load: K = 1,1 - 1,5

### **Additional information and ordering instructions**

Selection of driveshafts

The selection of a GWB® driveshaft is determined not only by the maximum permissible torque of the shaft and the connections but also by a variety of other factors.

For the exact determination and selection of driveshafts, see the Selection of Driveshafts pages in this brochure.

Dana engineers can precisely calculate the correct size of the shaft and joint for your application with the use of computer programs created specifically for this purpose.

In order to best match your requirements, you'll be asked to provide the following information:

- Installation length of the driveshaft
- Maximum joint angle requirement
- Required length compensation
- Maximum rotation speed of the shaft
- Shaft end connection details
- Maximum torque to be transmitted
- Nominal torque to be transmitted
- Load occurrences
- Description of the equipment and working conditions

### **Specific applications**

## Driveshafts in railway transmissions

The selection of driveshafts in the secondary system of railway vehicles must be based on the maximum torque that can be transmitted to the track (wheel slip or adhesion torque).

## Driveshafts in crane travel drives

The particular operating conditions for travel drives of cranes have been taken into consideration in the DIN-standard 15 450. As a result, driveshafts for these applications can be selected by using that standard.

## **Driveshafts in marine** transmissions

These driveshafts are subject to acceptance and must correspond to the standards of the respective classification society.

## Driveshafts for other forms of passenger conveyance

Driveshafts used in amusement park equipment, ski lifts or similar lift systems, elevators, and rail vehicles must be in accordance with the standards and specifications of the appropriate licensing and supervisory authorities.

### Driveshafts in explosive environments (Atex-outline)

For the use of driveshafts in areas with danger of explosion, an EC-conformity certificate acc. to EC-outline 94/9/EG can be provided. The possible categories for the product "driveshaft" are:

a) in general: (€ ⊗ II 3 GDc T6
 b) for driveshafts with adapted features: (€ ⊗ II 2 GDc T6

The driveshaft should not be used under the following operating conditions:

- Within the critical bending speed range of the drive
- Within the critical torsional speed range of the drive
- At operating angles which exceed the specified maximum (refer to drawing confirmed with order)
- At dynamic and static operating torques which exceed the specified limit (refer to drawing confirmed with order)
- At speed x deflection angle (n x β) conditions which exceed the limit (refer to GWB® catalog)
- For usage time which exceeds the calculated bearing lifetime of the joint bearings

If you'd like more information on GWB® driveshafts, or would like to discuss specific application requirements with an engineer, please call Dana at 0049 (0) 201-8124-0 or visit www.GWBdriveshaft.com, www.Dana.com.

### **About Dana Holding Corporation**

Dana is a global leader in the supply of highly engineered driveline, sealing, and thermal-management technologies that improve the efficiency and performance of vehicles with both conventional and alternative-energy powertrains. Serving three primary markets - passenger vehicle, commercial truck, and off-highway equipment - Dana provides the world's original-equipment manufacturers

and the aftermarket with local product and service support through a network of nearly 100 engineering, manufacturing, and distribution facilities. Founded in 1904 and based in Maumee, Ohio, the company employs 23,000 people in 26 countries on six continents. In 2013, Dana generated sales of \$6.8 billion. For more information, please visit dana.com.

© 2015 Dana Limited

### **About GWB® Products**

Dana produces GWB® industrial driveshafts and genuine service parts for the scrap steel, construction, railway, marine, and paper industries. Manufacturing and assembly operations in Germany are supported by Dana's global network of R&D and distribution facilities.
